# Dynamics and how to use the orbits of stars to do interesting things 

chapter 3 of $\mathrm{S}+\mathrm{G}$ - parts of ch 2 of $\mathrm{B} \& \mathrm{~T}$ and parts<br>of Ch 11 of MWB

## Galactic Rotation- Oort Constants

- using a bit of trig
$R(\cos \alpha)=R_{0} \sin (1)$
$R(\sin \alpha)=R_{0} \cos (1)-d$
so
$\mathrm{V}_{\text {observered,radial }}=\left(\omega-\omega_{0}\right) \mathrm{R}_{0} \sin (\mathrm{l})$
$V_{\text {observered,tang }}=\left(\omega-\omega_{0}\right) R_{0} \cos (1)-\omega d$
then following the text expand $\left(\omega-\omega_{0}\right)$ around $\mathrm{R}_{0}$ and using the fact that most of the velocities are local e.g. $R-R_{0}$ is small and $d$ is smaller than $R$ or $R_{0}$ (not TRUE for HI) and some more trig
get

$\mathrm{V}_{\text {observered, ,adial }}=\operatorname{Adsin}(21) ; \mathrm{V}_{\text {obs,tang }}=\operatorname{Adcos}(21)+\mathrm{Bd}$
Where
$\mathrm{A}=-1 / 2 \mathrm{R}_{0}(\mathrm{~d} \omega / \mathrm{dr})$ at $\mathrm{R}_{0}$
$B=-1 / 2 R_{0}(d \omega / d r-\omega)$

## Galactic Rotation Curve- sec 2.3.1 S+G

Assume gas/star has a perfectly circular orbit

At a radius $\mathrm{R}_{0}$ orbit with velocity $\mathrm{V}_{0}$; another star/ parcel of gas at radius R has a orbital speed $V(R)$

- Convert to angular velocity $\omega$
- $\mathrm{V}_{\text {observered., radial }}=\omega \mathrm{R}(\cos \alpha)-\omega_{0} \mathrm{R}_{0} \sin (\mathrm{I})$
- $\mathrm{V}_{\text {observered, tang }}=\omega \mathrm{R}(\sin \alpha)-\omega_{0} \mathrm{R}_{0} \cos (1)$

## In terms of Angular Velocity

- model Galactic motion as circular motion with monotonically decreasing angular rate with distance from center.
- Simplest physics: if the mass of the Galaxy is all at center angular velocity $\omega$ at R is $\omega=\mathrm{M}^{1 / 2} \mathrm{G}^{1 / 2} \mathrm{R}^{-3 / 2}$
- If looking through the Galaxy at an angle $l$ from the center, velocity at radius R projected along the line of site minus the velocity of the sun projected on the same line is
(1) $V=\omega R \sin d-\omega_{0} R_{o} \sin L$
$\omega=$ angular velocity at distance R
$\omega_{\mathrm{o}}=$ angular velocity at a distance $\mathrm{R}_{\mathrm{o}}$
$\mathrm{R}_{\mathrm{o}}=$ distance to the Galactic center

l = Galactic longitude
- Using trigonometric identity $\sin d=R_{o} \sin (1 / R)$ and substituting into equation (1)
- $\mathrm{V}=\left(\omega-\mathrm{w} \omega_{\mathrm{o}}\right) \mathrm{R}_{\mathrm{o}} \sin \mathrm{l}$
http://www.haystack.mit.edu/edu/ undergrad/srt/SRT Projects/ rotation.html

## Continued

- The tangential velocity $\mathrm{v}_{\mathrm{T}}=\mathrm{V}_{\mathrm{o}} \sin \alpha-\mathrm{V}_{\mathrm{o}} \cos \mathrm{l}$

$$
\text { and } R \sin \alpha=R_{0} \cos l-d
$$

- a little algebra then gives

$$
\mathrm{V}_{\mathrm{T}}=\mathrm{V} / \mathrm{R}\left(\mathrm{R}_{0} \cos \mathrm{l}-\mathrm{d}\right)-\mathrm{V}_{0} \cos \mathrm{l}
$$

- re-writing this in terms of angular velocity

$$
V_{T}=\left(\omega-\omega_{0}\right) R_{0} \cos l-\omega d
$$

- For a reasonable galactic mass distribution we expect that the angular speed $\omega=\mathrm{V} / \mathrm{R}$ is monotonically decreasing at large R (most galaxies have flat rotation curves (const V ) at large R ) then get a set of radial velocities as a function of where you are in the galaxy
- $\mathrm{V}_{\mathrm{T}}$ is positive for $0<1<90$ and nearby objects- if $\mathrm{R}>\mathrm{R}_{0}$ it is negative
- For $90<1<180 \mathrm{~V}_{\mathrm{T}}$ is always negative
- For $180<1<270 \mathrm{~V}_{\mathrm{T}}$ is always positive ( $\mathrm{S}+\mathrm{G} \sec 2.3 .1$ )

5

## Oort Constants S\&G pg 92-93

## Derivation:

- for objects near to sun, use a Taylor series expansion of $\omega-\omega_{0}$
$\omega-\omega_{\mathrm{o}}=\mathrm{d} \omega / \mathrm{dR}\left(\mathrm{R}-\mathrm{R}_{\mathrm{o}}\right)$
$\omega=\mathrm{V} / \mathrm{R} ; \mathrm{d} \omega / \mathrm{dR}=\mathrm{d} / \mathrm{dr}(\mathrm{V} / \mathrm{R})=(1 / \mathrm{R}) \mathrm{dV} / \mathrm{dr}-\mathrm{V} / \mathrm{R}^{2}$
then to first order
$\mathrm{V}_{\mathrm{r}}=\left(\omega-\omega_{\mathrm{o}}\right) \mathrm{R}_{\mathrm{o}} \sin \mathrm{l}=[\mathrm{dV} / \mathrm{dr}-\mathrm{V} / \mathrm{R}]\left(\mathrm{R}-\mathrm{R}_{\mathrm{o}}\right) \sin \mathrm{l}$; when $\mathrm{d} \ll \mathrm{R}_{\text {o }}$
$\mathrm{R}-\mathrm{R}_{\mathrm{o}}=\mathrm{d} \operatorname{cosl}$ which gives
$V_{r}=\left(V_{0} / R_{0}-d V / d r\right) d \sin l \cos l$
using trig identity $\sin l \cos l=1 / 2 \sin 2 l$

GC
one gets the Oort forumla
$\mathrm{V}_{\mathrm{r}}=\operatorname{Adsin} 2 \mathrm{l}$ where $A=\frac{1}{2}\left[\frac{V_{0}}{R_{0}}-\left(\frac{d V}{d R}\right)_{R_{0}}\right]$
One can do the same sort of thing for $\mathrm{V}_{\mathrm{T}}$

## Oort Constants

- For nearby objects ( $\mathrm{d} \ll \mathrm{R}$ )
- $\mathrm{V}(\mathrm{R}) \sim \mathrm{R}_{0} \sin 1(\mathrm{~d}(\mathrm{~V} / \mathrm{R}) / \mathrm{dr})\left(\mathrm{R}-\mathrm{R}_{0}\right)$
$\sim \mathrm{d} \sin (21)[-\mathrm{R} / 2(\mathrm{~d}(\mathrm{~V} / \mathrm{R}) / \mathrm{dr}) \sim \mathrm{d} \operatorname{Asin}(2 \mathrm{l})$
(l is the galactic longitude)
- A is one of 'Oorts constants'
- The other B (pg $93 \mathrm{~S}+\mathrm{G}$ ) is related to the tangential velocity of a object near the sun $\mathrm{V}_{\mathrm{t}}=\mathrm{d}[\mathrm{A} \cos (21)+\mathrm{B}]$
- So, stars at the same distance $r$ will show a systematic pattern in the magnitude of their radial velocities across the sky with Galactic longitude.
- A is the Oort constant describing the shearing motion and B describes the rotation of the Galaxy
$A=\frac{1}{2}\left[\frac{V_{\circ}}{R_{\circ}}-\left(\frac{d V}{d R}\right)_{R_{\circ}}\right]$

$$
B=-\frac{1}{2}\left[\frac{V_{\circ}}{R_{\circ}}+\left(\frac{d V}{d R}\right)_{R_{\circ}}\right]
$$

$$
A+B=-\left(\frac{d V}{d R}\right)_{R_{\circ}} \quad ; A-B=\frac{V_{\circ}}{R_{\circ}}
$$

$\mathrm{A}=-1 / 2[\mathrm{Rd} \omega / \mathrm{dr}]$
Useful since if know A get kinematic estimate of $d$

Radial velocity $\mathrm{v}_{\mathrm{r}} \sim 2 \mathrm{AR}_{0}(1-\sin \mathrm{l})$ only valid near $1 \sim 90$ measure
$\mathrm{AR}_{0} \sim 115 \mathrm{~km} / \mathrm{s}$

## Oort 'B'

- B measures 'vorticity' $\mathrm{B}=-(\omega=-1 / 2[\mathrm{Rd} \omega / \mathrm{dr}])=-1 / 2[(\mathrm{~V} / \mathrm{R})+(\mathrm{dV} / \mathrm{dR})]$ angular momentum gradient
$\omega=\mathrm{A}-\mathrm{B}=\mathrm{V} / \mathbf{R}$; angular speed of Local standard of rest (sun's motion)

Oort constants are local description of differential rotation Values
$\mathrm{A}=14.8 \mathrm{~km} / \mathrm{s} / \mathrm{kpc}$
$\mathrm{B}=-12.4 \mathrm{~km} / \mathrm{s} / \mathrm{kpc}$
Velocity of sun $\mathbf{V}_{0}=\mathrm{R}_{\mathbf{0}}(\mathrm{A}-\mathrm{B})$

I will not cover epicycles (stars not on perfect circular orbits) now (maybe next lecture): : see sec pg 133ff in S\&G

## A Guide to the Next Few Lectures

-The geometry of gravitational potentials : methods to derive gravitational potentials from mass distributions, and visa versa.
-Potentials define how stars move
consider stellar orbit shapes, and divide them into orbit classes.
-The gravitational field and stellar motion are interconnected :
the Virial Theorem relates the global potential energy and kinetic energy of the system.

- The Distribution Function (DF) :
the DF specifies how stars are distributed throughout the system and with what velocities.
For collisionless systems, the DF is constrained by a continuity equation : the Collisionless Boltzmann Equation
-This can be recast in more observational terms as the Jeans Equation.
The Jeans Theorem helps us choose DFs which are solutions to the continuity equations

## A Reminder of Newtonian Physics sec 2.1 in B\&T

Newtons law of gravity tells us that two masses attract each other with a force

$$
\frac{d}{d t}(m v)=-\frac{G m M}{r^{3}} r
$$

$\phi(\mathbf{x})$ is the potential
If we have a collection of masses acting on a mass $\mathrm{m}_{\alpha}$ the force is

$$
\begin{aligned}
& \frac{d}{d t}\left(m_{\alpha} v_{\alpha}\right)=-\sum_{\beta} \frac{G m_{\alpha} M_{\beta}}{\left|\boldsymbol{x}_{\alpha}-x_{\beta}\right|^{3}}\left(\boldsymbol{x}_{\alpha}-x_{\beta}\right), \alpha \neq \beta \\
& \frac{d}{d t}(m \boldsymbol{v})=-m \nabla \Phi(\boldsymbol{x}), \quad \text { Gauss's thm } \int \nabla \phi \bullet \mathrm{ds}^{2}==4 \pi \mathrm{GM} \\
& \text { with } \\
& \Phi(\boldsymbol{x})=-\sum_{\alpha} \frac{G m_{\alpha}}{\left|\boldsymbol{x}-\boldsymbol{x}_{\alpha}\right|} \text {, for } \mathbf{x} \neq \boldsymbol{x}_{\alpha} \quad \text { over a closed surface }=4 \pi \mathrm{G} \text { x mass within }
\end{aligned}
$$

the gravitational potential. If we can approximate the discrete stellar distribution with a continuous distribution $\rho$.

$$
\begin{equation*}
\Phi(\mathbf{x})=-\int \frac{G \rho\left(\mathbf{x}^{\prime}\right)}{\left|\boldsymbol{x}-\boldsymbol{x}^{\prime}\right|} d^{3} \mathbf{x}^{\prime} \tag{11}
\end{equation*}
$$

## Conservation of Energy and Angular Momentum Sec 3.1 S\&G

In the absence of external forces a star will conserve energy along its orbit

$$
\begin{aligned}
& v \cdot \frac{d}{d t}(m v)=-m v \cdot \nabla \Phi(x), \\
& v \cdot \frac{d}{d t}(m v)+m v \cdot \nabla \Phi(x)=0 \\
& \text { But since } \frac{\boldsymbol{d} \boldsymbol{\Phi}}{\boldsymbol{d} \boldsymbol{t}}=\boldsymbol{v} \cdot \boldsymbol{\Phi}(\mathbf{x}) \quad \nabla=\hat{\mathbf{x}} \frac{\partial}{\partial x}+\hat{\mathbf{y}} \frac{\partial}{\partial y}+\hat{\mathbf{z}} \frac{\partial}{\partial z} \\
& \frac{d}{d t}\left[\frac{m}{2}\left(v^{2}\right)+m \Phi(x)\right]=0 \\
& \text { whee }\{\hat{X}, \hat{y}, \hat{z}) \text { reethe unt vecons inther respectivedicedions: } \\
& \text { This is just the } \mathrm{KE}+\mathrm{PE}
\end{aligned}
$$

$$
\frac{d L}{d t}=x \times m \frac{d v}{d t}=-m x \times \nabla \Phi
$$

Angular momentum L

## Some Basics - M. Whittle

- The gravitational potential energy is a scalar field
- its gradient gives the net gravitational force (per unit mass) which is a vector field :

$$
\frac{\partial^{2}}{\partial x^{2}}+\frac{\partial^{2}}{\partial y^{2}}+\frac{\partial^{2}}{\partial z^{2}}=\nabla \cdot \nabla=\nabla^{2}
$$

$$
\Phi(\mathbf{r})=-G \int_{V} \frac{\rho\left(\mathbf{r}^{\prime}\right)}{\left|\mathbf{r}^{\prime}-\mathbf{r}\right|} d^{3} \mathbf{r}^{\prime}
$$

$$
\mathbf{F}(\mathbf{r})=-\nabla \Phi(\mathbf{r})=G \int_{V} \frac{\mathbf{r}^{\prime}-\mathbf{r}}{\left|\mathbf{r}^{\prime}-\mathbf{r}\right|^{3}} \rho\left(\mathbf{r}^{\prime}\right) d^{3} \mathbf{r}^{\prime}
$$

$$
\nabla \cdot \mathbf{F}(\mathbf{r})=-4 \pi G \rho(\mathbf{r})
$$

$$
\nabla^{2} \Phi(\mathbf{r})=4 \pi G \rho(\mathbf{r}) \longleftrightarrow \begin{gathered}
\text { Poissons eq inside the mass } \\
\text { distribution }
\end{gathered}
$$

distribution

$$
\nabla^{2} \Phi(\mathbf{r})=0 \longleftrightarrow \text { Outside the mass dist }
$$

## Poisson's Eq+ Definition of Potential Energy (W)

So the force per unit mass is

$$
\boldsymbol{F}(\boldsymbol{x})=-\nabla \Phi(\boldsymbol{x})=\int G \rho\left(\boldsymbol{x}^{\prime}\right) \frac{\left(\boldsymbol{x}-\boldsymbol{x}^{\prime}\right)}{|\boldsymbol{x}-\boldsymbol{x}|^{3}} d^{3} \boldsymbol{x}^{\prime}
$$

To get the differential form we start with the definitic of $\Phi$ and applying $\nabla^{2}$ to both sides S+G pg 112-113

$$
\begin{aligned}
\nabla^{2} \Phi(\mathbf{x}) & =-\nabla^{2} \int \frac{G \rho\left(\mathbf{x}^{\prime}\right)}{\left|\boldsymbol{x}-x^{\prime}\right|} d^{3} \boldsymbol{x}^{\prime} \\
& =4 \pi G \rho(\mathbf{x}) \quad \text { Poisson's equation. }
\end{aligned}
$$

Potential energy W

$$
W=\frac{1}{2} \int_{V} \rho(\mathbf{r}) \Phi(\mathbf{r}) d^{3} \mathbf{r}=-\frac{1}{8 \pi G} \int_{V}|\nabla \Phi|^{2} d^{3} \mathbf{r}
$$

## Derivation of Poisson's Eq

So the force per unit mass is

$$
\boldsymbol{F}(\boldsymbol{x})=-\nabla \Phi(\boldsymbol{x})=\int G \rho\left(\boldsymbol{x}^{\prime}\right) \frac{\left(\boldsymbol{x}-\boldsymbol{x}^{\prime}\right)}{|\boldsymbol{x}-\boldsymbol{x}|^{3}} d^{3} \boldsymbol{x}^{\prime}
$$

To get the differential form we start with the definiti of $\Phi$ and applying $\nabla^{2}$ to both sides

$$
\begin{aligned}
\nabla^{2} \Phi(\mathbf{x}) & =-\nabla^{2} \int \frac{G \rho\left(\mathbf{x}^{\prime}\right)}{\left|\boldsymbol{x}-x^{\prime}\right|} d^{3} \mathbf{x}^{\prime} \\
& =4 \pi G \rho(\mathbf{x}) \quad \text { Poisson's equation. }
\end{aligned}
$$

see S+G pg 112 for detailed derivation

Characteristic Velocities
$\mathbf{v}_{\text {circular }}=\mathbf{r} \mathbf{d} \Phi(\mathbf{r}) / \mathbf{d t}=\mathrm{GM} / \mathrm{r} ; \mathrm{v}=\mathrm{sqrt}(\mathrm{GM} / \mathrm{r})$ Keplerian
velocity dispersion $\sigma^{2}=(1 / \rho) \int \rho(\partial \Phi(r, z) / \partial z) d z$ or alternatively $\sigma^{2}(R)=\left(4 \pi G / 3 M(R) \int r \rho(r) M(R) d r\right.$
escape speed $=\mathrm{v}_{\text {esc }}=\operatorname{sqrt}(2 \Phi(\mathrm{r}))$ or $\Phi(\mathrm{r})=1 / 2 \mathrm{v}^{2}{ }_{\text {esc }}$ so choosing $r$ is crucial

## More Newton-Spherical Systems B\&T 2.2

Newtons 1st theorem: a body inside a spherical shell has no net gravitational force from that shell; e.g. $\nabla \Phi(\mathrm{r})=0$

Newtons 2nd theorem: the gravitational force on a body outside a spherical shell is the same as if all the mass were at a point at the center of the shell.

Simple examples:
Point source of mass M; potential $\Phi(\mathrm{r})=-\mathrm{GM} / \mathrm{r}$;
definition of circular speed; speed of a test particle on a circular orbit at radius $r$
$\mathbf{v}^{2}{ }_{\text {circular }}=\mathbf{r} \mathbf{d} \Phi(\mathbf{r}) / \mathbf{d t}=\mathrm{GM} / \mathbf{r} ; \mathrm{v}_{\text {circular }}=\mathrm{sqrt}(\mathrm{GM} / \mathrm{r}) ;$ Keplerian
velocity dispersion $\sigma^{2}=(1 / \rho) \int \rho(\partial \Phi(\mathbf{r}, \mathrm{z}) / \partial \mathrm{z}) \mathrm{dz}$
escape speed $=\operatorname{sqrt}[2 \Phi(\mathrm{r})]=\operatorname{sqrt}(2 \mathrm{GM} / \mathrm{r})$; from equating kinetic energy to potential energy $1 / 2 \mathrm{mv}^{2}=|\Phi(\mathrm{r})|$

## Escape Speed

- As r goes to infinity $\phi(\mathrm{r})$ goes to zero
- so to escape $\mathrm{v}^{2}>2 \phi(\mathrm{r})$; e.q. $\mathrm{v}_{\text {esc }}=$ sqrt $(-2 \phi(\mathrm{r}))$

## Gravity and Dynamics-Spherical Systems- Repeat

- Newtons $1^{\text {st }}$ theorm : a body inside a a spherical shell has no net force from that shell $\nabla \phi=0$
- Newtons $2^{\text {nd }}$ theorm ; a body outside the shell experiences forces as if they all came from a point at the center of the shell-Gravitational force at a point outside a closed sphere is the same as if all the mass were at the center
- This does not work for a thin disk- cannot ignore what is outside of a given radius
- One of the prime observables (especially for spirals) is the circular velocity; in general $V^{2}(R) / R=G(M<R) / R^{2}$
more accurate estimates need to know shape of potential
- so one can derive the mass of a flattened system from the rotation curve
- point source has a potential $\phi=-\mathrm{GM} / \mathrm{r}$
- A body in orbit around this point mass has a circular speed $\mathrm{v}_{\mathrm{c}}{ }^{2}=\mathrm{r} \phi \mathrm{d} / \mathrm{dr}=\mathrm{GM} / \mathrm{r}$
- $\mathrm{v}_{\mathrm{c}}=\mathrm{sqrt}(\mathrm{GM} / \mathrm{r})$; Keplerian
- Escape speed from this potential $\mathrm{v}_{\text {escape }}=\mathrm{sqrt}(2 \phi)=\operatorname{sqrt}(2 \mathrm{GM} / \mathrm{r})$ (conservation of energy $\mathrm{KE}=1 / 2 \mathrm{mv}^{2}{ }_{\text {escape }}$

## Homogenous Sphere B\&T sec 2.2.2

- Constant density sphere of radius a and density $\rho_{0}$
- $\mathrm{M}(\mathrm{r})=4 \pi \mathrm{Gr}^{3} \rho_{0} ; \mathrm{r}<\mathrm{a}$
- $\mathrm{M}(\mathrm{r})=4 \pi \mathrm{Ga}^{3} \rho_{0} ; \mathrm{r}>\mathrm{a}$
$\left.\phi(\mathrm{R})=-\mathrm{d} / \mathrm{dr}(\mathrm{M}(\mathrm{R})) ; \phi(\mathrm{R})=-3 / 5 \mathrm{GM}^{2} / \mathrm{R} ; \mathrm{B} \& \mathrm{~T} 2.41\right)$
$\mathrm{R}>\mathrm{a} \phi(\mathrm{r})=4 \pi \mathrm{Ga}^{3} \rho_{0}=-\mathrm{GM} / \mathrm{r}$
$\mathrm{R}<\mathrm{a} \phi(\mathrm{r})=-2 \pi G \rho_{0}\left(\mathrm{a}^{2}-1 / 3 \mathrm{r}^{2}\right)$ );
$\mathrm{v}_{\text {circ }}^{2}=(4 \pi / 3) \mathrm{G} \mathrm{\rho}_{0} \mathrm{r}^{2}$; solid body rotation $\mathrm{R}<a$
Orbital period $\mathbf{T}=\mathbf{2} \boldsymbol{\pi r} / \mathbf{v}_{\text {circ }}=\mathbf{s q r t}\left(\mathbf{3} \pi / \mathbf{G} \rho_{0}\right)$
Dynamical time $=$ crossing time $=T / 4=\mathbf{s q r t}\left(\mathbf{3} \boldsymbol{\pi} / \mathbf{1 6 G} \rho_{0}\right)$
Potential is the same form as an harmonic oscillator with angular freq $2 \pi / \mathrm{T}$ ( $\mathrm{B} \& \mathrm{~T} 2.2 .2(\mathrm{~b})$ )
Regardless of r a particle will reach $\mathrm{r}=0$ (in free fall) in a time $T=/ 4$
Eq of motion of a test particle INSIDE the sphere is $\mathrm{dr}^{2} / \mathrm{dt}^{2}=-\mathrm{GM}(\mathrm{r}) / \mathrm{r}^{2}=-(4 \pi / 3) \mathrm{G} \rho_{0} \mathrm{r}$
General result dynamical time $\sim \operatorname{sqrt}(1 / \mathrm{G} \rho)$

## Some Simple Cases

- Constant density sphere of radius a and density $\rho_{0}$ continued

Potential energy (B\&T) eq 2.41, 2.32
$\phi(\mathrm{R})=-\mathrm{d} / \mathrm{dr}(\mathrm{M}(\mathrm{R}))$;
$\mathrm{R}>\mathrm{a} \phi(\mathrm{r})=4 \pi \mathrm{Ga}^{3} \rho_{0}=-\mathrm{GM} / \mathrm{r}$
$\mathrm{R}<\mathrm{a} \phi(\mathrm{r})=-2 \pi G \rho_{0}\left(\mathrm{a}^{2}-1 / 3 \mathrm{r}^{2}\right)$ );
$\mathrm{v}_{\text {circ }}^{2}=(4 \pi / 3) \mathrm{G} \mathrm{\rho}_{0} \mathrm{r}^{2}$ solid body rotation
Potential is the same form as a harmonic oscillator e.g. the eq of motion is $\mathrm{d}^{2} \mathrm{r} / \mathrm{dt}^{2}=-\mathrm{GM}(\mathrm{r}) / \mathrm{r}=4 \pi / 3 \mathrm{Gr} \rho$; solution to harmonic oscillator is
$\mathrm{r}=\mathrm{Acos}(\omega \mathrm{t}+\phi)$ with $\omega=\operatorname{sqrt}(4 \pi / 3 \mathrm{G} \rho)=2 \pi / \mathrm{T}$
$\mathrm{T}=\operatorname{sqrt}\left(3 \pi / \mathrm{G} \rho_{0}\right)=2 \pi \mathrm{r} / \mathrm{v}_{\text {circ }}$

## Spherıcal Systems:Homogenous sphere of radius 'a' Summary

- $\mathrm{M}(\mathrm{r})=4 / 3 \pi \mathrm{r}^{3} \rho(\mathrm{r}<a) ; \mathrm{r}>\mathrm{a}(\mathrm{r})=4 / 3 \pi r^{3} \mathrm{a}$
- Inside body $(\mathrm{r}<\mathrm{a}) ; \phi(\mathrm{r})=-2 \pi G \rho\left(\mathrm{a}^{2}-1 / 3 \mathrm{r}^{2}\right)$ (from eq. 2.38 in $\mathrm{B} \& \mathrm{~T}$ )

Outside $(r>a) ; ~) \phi(r)=-4 \pi G \rho\left(a^{3} / 3\right)$
Solid body rotation $v_{c}^{2}=-4 \pi G \rho\left(r^{2} / 3\right)$
Orbital period $\mathrm{T}=2 \pi \mathrm{r} / \mathrm{v}_{\mathrm{c}}=\mathrm{sqrt}(3 \pi / \mathrm{G} \rho)$;
a crossing time (dynamical time) $=\mathrm{T} / 4=\operatorname{sqrt}(3 \pi / 16 \mathrm{G} \rho)$
potential energy $\mathrm{W}=-3 / 5 \mathrm{GM}^{2} / \mathrm{a}$
The motion of a test particle inside this sphere is that of a simple harmonic
oscillator $\mathrm{d}^{2} \mathrm{r} / \mathrm{dt}^{2}=-\mathrm{G}\left(\mathrm{M}(\mathrm{r}) / \mathrm{r}^{2}=4 \pi \mathrm{G} \rho \mathrm{r} / 3\right.$ with angular freq $2 \pi / \mathrm{T}$
no matter the intial value of $r$, a particle will reach $r=0$ in the dynamical time T/4
In general the dynamical time $\mathrm{t}_{\mathrm{dyn}} \sim 1 / \operatorname{sqrt}(\mathrm{G}<\rho>)$
and its 'gravitational radius' $\mathrm{r}_{\mathrm{g}}=\mathrm{GM}^{2} / \mathrm{W}$

## Summary of Dynamical Equations

- gravitational pot'l $\Phi(r)=-G \int \rho(r) /\left|r-r^{\prime}\right| d^{3} r$
- Gravitational force $\mathrm{F}(\mathrm{r})=-\nabla \Phi(\mathrm{r})$
- Poissons Eq $\nabla^{2} \Phi(r)=4 \pi G \rho$; if there are no sources

$$
\text { Laplace Eq } \nabla^{2} \Phi(r)=0
$$

- Gauss's theorem : $\int \nabla \Phi(r) \cdot{ }^{\bullet} \mathrm{ds}^{2}=4 \pi \mathrm{GM}$
- Potential energy $\mathbf{W}=1 / 2 \int \mathbf{r} \rho(\mathrm{r}) \nabla \Phi d^{3} \mathbf{r}$
- In words Gauss's theorem says that the integral of the normal component of $\nabla \Phi$ over a closed surface equals $4 \pi G$ times the mass enclosed

## Potentials are Separable

- We make the fundamental assumption that the potential of a system can be decomposed into separable parts-
- This is because Poisson's equation is linear:
- differences between any two $\phi-\rho$ pairs is also a $\phi-\rho$ pair, and differentials of $\phi-\rho$ or are also $\phi-\rho$ pairs
- e.g. $\phi_{\text {total }}=\phi_{\text {bulge }}+\phi_{\text {disk }}+\phi_{\text {halo }}$

## So Far Spherical Systems

- But spiral galaxies have a significant fraction of the mass (?; at least the baryons) in a flattened system.

## Kuzmin Disk B\&T sec 2.3 S\&G Prob 3.4;

- This ansatz is for a flattened system and separates out the radial and $z$ directions
- Assume $\phi_{\mathrm{K}}(\mathrm{z}, \mathrm{R})=\mathrm{GM} /\left[\operatorname{sqrt}\left(\mathrm{R}^{2}+(\mathrm{a}+\mathrm{z})^{2}\right)\right]$; axisymmetric (cylindrical)
$R$ is in the $x, y$ plane
- Analytically, outside the plane, $\phi_{\mathrm{K}}$ has the form of the potential of a point mass
displaced by a distance ' a ' along the z axis

$$
- \text { e.q. } R(z)=\left\{\begin{array}{c}
(0, a) ; z<0 \\
(0,-a) ; z>0
\end{array}\right.
$$

- Thus $\nabla^{2} \Phi=0$ everywhere except along $\mathrm{z}=0$ Poisson's eq
- Applying Gauss's thm $\int \nabla \Phi d^{2} \mathrm{~s}=4 \pi \mathrm{GM}$ and get $\Sigma(\mathrm{R})=\mathrm{aM} /\left[2 \pi\left(\mathrm{R}^{2}+\mathrm{a}^{2}\right)^{3 / 2}\right]$
this is in infinitely thin disk... not too bad an approx

Use of Gauss's thm (divergence) the sum of all sources minus the sum of all sinks gives the net flow out of a region.

$\int \nabla \Phi \mathrm{d}^{2} \mathrm{~s}=4 \pi \mathrm{GM}=2 \pi \mathrm{G} \Sigma$ as $Z \longrightarrow 0 ; \boldsymbol{\Sigma}=(\mathbf{1} / \mathbf{2} \boldsymbol{\pi}) \mathbf{G} \mathbf{d} \boldsymbol{\Phi}^{\mathbf{6}} / \mathbf{d r}$

## Flattened +Spherical Systems-Binney and Tremaine eqs

- Add the Kuzmin to the Plummer potential (S\&G $113,114)$
- When $\mathrm{b} / \mathrm{a} \sim 0.2$, qualitatively similar to the light distributions of disk galaxies,

$$
\begin{equation*}
\Phi_{\mathrm{M}}(R, z)=-\frac{G M}{\sqrt{R^{2}+\left(a+\sqrt{z^{2}+b^{2}}\right)^{2}}} . \tag{2.69a}
\end{equation*}
$$

When $a=0, \Phi_{\mathrm{M}}$ reduces to Plummer's spherical potential (2.44a), and when $b=0, \Phi_{\mathrm{M}}$ reduces to Kuzmin's potential of a razor-thin disk (2.68a). Thus, depending on the choice of the two parameters $a$ and $b, \Phi_{\mathrm{M}}$ can represent the potential of anything from an infinitesimally thin disk to a spherical system. If we calculate $\nabla^{2} \Phi_{\mathrm{M}}$, we find that the mass distribution with which it is associated is (Miyamoto \& Nagai 1975)

$$
\begin{equation*}
\rho_{\mathrm{M}}(R, z)=\left(\frac{b^{2} M}{4 \pi}\right) \frac{a R^{2}+\left(a+3 \sqrt{z^{2}+b^{2}}\right)\left(a+\sqrt{z^{2}+b^{2}}\right)^{2}}{\left[R^{2}+\left(a+\sqrt{z^{2}+b^{2}}\right)^{2}\right]^{5 / 2}\left(z^{2}+b^{2}\right)^{3 / 2}} . \tag{2.69b}
\end{equation*}
$$

Contours of equal density in the (R; z) plane for $b / a=0.2$

## Explaining Disks

- Remember the most important properties of disk dominated galaxies (MBW pg 495)
- More luminous disks are on average
- larger, redder, rotate faster, smaller gas fraction
- flat rotation curves
- surface brightness profiles close to exponential
- lower metallicity in outer regions
- traditional to model them as an infinitely thin exponential disk with a surface density distribution $\Sigma(\mathrm{R})=\Sigma_{0 \mathrm{y}} \exp \left(-\mathrm{R} / \mathbf{R}_{\mathbf{d}}\right)$
- This gives a potential (MBW pg 496) which is a bit messy
$\phi(\mathrm{R}, \mathrm{z})=-2 \pi \mathrm{G} \Sigma_{0}{ }^{2} \mathrm{R}_{\mathrm{D}} \int\left[\mathrm{J}_{0}(\mathrm{kR}) \exp (-\mathrm{klz})\right] /\left[1+\left(\mathrm{k} \mathbf{R}_{\mathrm{D}}\right)^{2}\right]^{3 / 2} \mathrm{dk}$
$\mathrm{J}_{0}$ is a Bessel function order zero

## Modeling Spirals

- to fit the observed density and velocity distributions in the MW one needs a 3 component mass distribution
- Traditionally this is parameterized as the sum of
$-\operatorname{disk} \Sigma(\mathrm{R})=\Sigma_{0}\left[\exp -\mathrm{R} / \mathbf{R}_{\mathrm{d}}\right]$
- spheroid (bulge) using $\mathrm{I}(\mathrm{R})=\mathrm{I}_{0} \mathrm{R}_{\mathrm{s}}{ }^{2} /\left[\mathrm{R}+\mathrm{R}_{\mathrm{s}}\right]^{2}$ or similar forms
- dark matter halo

$$
\rho(\mathrm{r})=\rho(0) /\left[1+(\mathrm{r} / \mathrm{a})^{2}\right]
$$

- See B\&T sec 2.7 for more complex forms- 2 solutions in B\&T- notice extreme difference in importance of halo (H) (table 2.3)
