

Relativity- Big Picture < today

http://hyperphysics.phyastr.gsu.edu/hbase/relativ/relcon.html#c1

No Aether

 Ernst Mach in 1883 argued that absolute time and space are meaningless and only relative motion is a useful concept

Einstein enters the picture...

Albert Einstein (1879-1955)

- * Three papers in 1905: Brownian Motion, Photoelectric
 - Effect (showing that light is quantized in energy- Nobel Prize), Special Theory of Relativity.
 - Didn't like idea of a luminiferous ether*
 - + Knew that Maxwell's equations were not invariant under a Galilean transform but were invariant under a "Lorentz transformation" of space and time- a transform is the formula for the conversion of coordinates and times of events.
- Problem: Newton's Laws are invariant under a Galilean transform if Maxwell's laws are 'correct' Newton's are not

its a pretty complex argument see http:///en.wikipedia.org/wiki/Luminiferous_aether#Einstein.27s_views_on_the_agther

Problems with the aether

Any aether would need to be

 massless, incompressible, entirely transparent, continuous, devoid of viscosity and nearly infinitely rigid and thus not like any known substance.

In 1905 Albert Einstein realised that Maxwell's equations did not require an aether. On the basis of Maxwell's equations he showed that the Lorentz Transformation was sufficient to explain that length contraction occurs and clocks appear to go slow provided that the old Galilean concept of how velocities add together was abandoned.

- + Einstein's remarkable achievement was to be the first physicist to propose <u>that Galilean relativity</u> might only be an approximation to reality.
- + Using the Lorentz Transformation instead Einstein found that these equations only contain relationships between space and time without any references to the properties of an aether.
- The possibility that phenomena such as length contraction could be due to the physical effects of spacetime geometry rather than the increase or decrease of forces between objects was as unexpected for physicists in 1908 as it is for the modern school student

paraphrase of http://en.wikibooks.org/wiki/Special_Relativity/Introduction

Invariant Under a Transform???

 ★ Example: the area of a triangle under a Galilean transform if x'=x+∆x,y'=y+dy

the area of the triangle remains the same

- Not invariant: a sum of numbers when I add 1 to each of them; e.g the transform x'=x+1 changes the total sum BUT the ordering (cardinal number e.g. first, second, third) is the same
- Angles and ratios of distances are invariant under scalings, rotations, translations and reflections. These transformations produce similar shapes. All circles can be transformed into each other and the ratio of the circumference to the diameter is invariant and equal to pi.

Einstein enters the picture...

Albert Einstein (1879-1955)

How to resolve conflict between mechanics and electromagnetism?

- +Throw away the idea of Galilean Relativity for mechanics!!! Galilean transformation between frames does not hold: velocities do not simply add/subtract (although the effects are small when the speeds are much less than the speed of light).
- + Came up with the two "Postulates of Relativity"
- Special Relativity is a theory of exceptional elegance, crafted from simple postulates about the constancy of physical laws and of the speed of light Its fundamental the laws of physics and the constancy of the speed of light are now understood in terms of the most basic symmetries in space and time.

EINSTEIN'S POSTULATES OF RELATIVITY

- Postulate 1 The laws of nature are the same in all *inertial* frames of reference
- Postulate 2 The speed of light in a vacuum is the same in all *inertial* frames of reference.
- The second postulate is necessary to allow Maxwell's equations to follow Postulate 1
- + Let's start to think about the consequences of these postulates.
- We will perform "thought experiments" (Gedankenexperimenten) to think of what observers moving at different speeds will think
- For now, we will ignore effect of gravity we suppose we are performing these experiments in the middle of deep space (or in free fall- remember gravity has the effect of creating an 'non-inertial frame which complicates things (and requires General Relativity to get correct)

Why don't we ordinarily notice time dilation?

Some examples of speeds in m/s

Lets work through some of the examples -

0.0055m/s world record speed of the fastest snail in the Congham,UK

0.080 m/s the top speed of a sloth (= 8.0 cm/s)

- + 1 m/s a typical human walking speed
- 28 m/s a car travelling at 60 miles per hour (mi/h or mph) or 100 kilometres per hour (km/h); also the speed a cheetah can maintain
- + 343 m/s the approximate speed of sound under standard conditions, which varies according to air temperature
- + 464 m/s Earth's rotation at the equator.
- + 559 m/s the average speed of Concorde's record Atlantic crossing (1996)
- + 1000 m/s the speed of a typical rifle bullet
- + 8000 m/s the speed of the Space Shuttle just before it enters orbit.
- + 11,082 m/s High speed record for manned vehicle, set by Apollo 10
- + 29,800 m/s Speed of the Earth in orbit around the Sun (about 30 km/s)
- + In particle accelerators the Lorentz factor can be ~10⁴; what is the velocity?
- + 299,792,458 m/s the speed of light (about 300,000 km/s)

 In the moving train analogy in the text(pg185)- we shine a light to the front and the back of the train car-the speed of the train is NOT added to the speed of lightlight moves at the same speed.

- Since the train is moving the stationary observer will observe the light to strike the rear of the train before it hits the front
- For the passenger the light strikes the front and the back at the same time, for the stationary observer they occur at different times!
- Time itself is different for the two observers

19

The train-and-platform experiment from E the reference frame of an observer onboard the train

 When the power of this machine is discussed, the energy of each proton is often mentioned: The protons each have an energy of 7 TeV. What does that mean?

LHC

With E = 7 TeV: E=γmc²
 the Lorentz factor has a
 value of about 7460
 corresponding to v =
 0.999999991 times the
 speed of light

 time passes 7460 times more slowly for the particles than it does for us observers.

A clock traveling at that speed from Earth to Proxima Centauri would measure a journey time of under 5 hours, while an observer who would remain on Earth would have aged over 4 years (Proxima Centauri is about 4.243 light-years away from us).

Examples of time dilation

The Muon Experiment

- Muons are created in upper atmosphere from cosmic ray hits
 Typical muon travel speeds are 0.99995×c, giving γ=100
- Half-life of muons in their own rest frame (measured in lab) is t_h=
 1.56 microseconds =0.00000156s
- Traveling at 0.99995×c for t_h=0.00000156s, the muons would go only 468 m
- + But traveling for $\gamma \times t_h = 0.000156s$, the muons can go 46 km
- + They easily reach the Earth's surface, and are detected!
- + Half-life can be measured by comparing muon flux on a mountain and at sea level; result agrees with $\gamma \times t_h$
- Why muons- have comparatively long decay life time (the second longest known) and are relatively weakly interacting so they can penetrate the atmospher
