The PM Method, Continued

There are several distinct steps in PM process:

1. Assign particles to mesh to compute ρ_i .
2. Get boundary conditions for Φ (Φ_0 and Φ_{N+1}).
3. Solve discretized version of Poisson's equation.
4. Compute \mathcal{F} from discretized version of force equation.

Step 1: Assigning particles to mesh

Discuss two schemes here:

1. Nearest Grid Point (NGP) scheme:

- Assign entire mass of particle to grid zone that contains it.
- E.g., discretize space into N zones in x -dimension:

Set $\rho_i = n_i m / \Delta x$, where n_i = number of particles in cell i (equal mass).

- Leads to a very coarse distribution of ρ_i :

2 Cloud-In-Cell (CIC) or Particle-In-Cell (PIC):

- Assign a “shape” or “cloud” to particle.
- Assume a distribution of ρ inside this shape.
- Then distribute mass to zones according to overlap.
- E.g., assume particle has top-hat ρ distribution, width w , height $\rho_0 = m/w$:

- Then (in 1-D), $\int_{-\infty}^{\infty} \rho(x) dx = m$. Distribute mass of particle according to overlap:

Leads to smoother ρ_i .

- Can adopt more complex shapes for density. E.g.,

Triangle

Gaussian

etc.

Higher-order “shapes” introduce ringing into system.

Step 2: Boundary conditions

- Given ρ_i , $i = 1, \dots, N$, need a boundary value for Φ , i.e., need Φ_0 and Φ_{N+1} .
- Often can use periodic BC, i.e., $\Phi_0 = \Phi_N$, $\Phi_{N+1} = \Phi_1$.
Appropriate for, e.g., cosmology simulations.
- Otherwise, standard to use multipole expansion (e.g., Jackson 1975) to compute potential on boundary due to mass in each cell.
 - Often, first (monopole) term is good enough:

$$\Phi_B(\mathbf{r}) = -\frac{GM}{|\mathbf{r} - \mathbf{r}_{CM}|}.$$

- See Binney & Tremaine (second ed), Ch .24, Eq. 2.95 for full series (involves spherical harmonics).

- There is an extremely efficient algorithm for solving tri-di systems.
 - Write discretized system as:

$$a_i \Phi_{i-1} + b_i \Phi_i + c_i \Phi_{i+1} = d_i.$$

- Then forward elimination gives (Hockney & Eastwood, p. 185):^a

$$w_1 = \frac{c_1}{b_1} \qquad w_i = \frac{c_i}{b_i - a_i w_{i-1}},$$

($i = 2, 3, \dots, N - 1$), and,

$$g_1 = \frac{d_1}{b_1} \qquad g_i = \frac{d_i - a_i g_{i-1}}{b_i - a_i w_{i-1}}.$$

^aAlso see `tridag ()` (*NRiC* §2.4).

- Backsubstitution:

$$\begin{aligned}\Phi_N &= g_N \\ \Phi_i &= g_i - w_i \Phi_{i+1},\end{aligned}$$

with $i = N - 1, N - 2, \dots, 1$.

- If a, b, c constant, can precompute w_i and $1/(b_i - a_i w_{i-1})$.
- If $a = 1, b = -2, c = 1$, only need $4N$ operations.
- For periodic BC, even simpler method possible (Hockney & Eastwood, p. 35).

Step 4: Force interpolation

- Once potential is given, must compute force (per unit mass) from $\mathcal{F} = -\nabla\Phi$.
- In 1-D, $\mathcal{F} = -\partial\Phi/\partial x \Rightarrow$ FDE $\mathcal{F}_{i+1/2} = -(\Phi_{i+1} - \Phi_i)/\Delta x$.
 - Forces centered at cell boundaries:

- Must interpolate forces to particle positions.

- Linear interpolation simplest. For each particle, position $x_{i-1/2} < x < x_{i+1/2}$, compute:

$$\mathcal{F}(x) = \mathcal{F}_{i-1/2} + \left(\frac{x - x_{i-1/2}}{\Delta x} \right) (\mathcal{F}_{i+1/2} - \mathcal{F}_{i-1/2}).$$

- Higher-order interpolation used in conjunction with higher-order charge-assignment schemes.

We now have ingredients necessary for a 1-D PM code:

1. Particle assignment;
2. Boundary conditions;
3. Solve Poisson's equation;
4. Force interpolation.

Result is \mathcal{F} for every particle.

Generalizing to 3-D

- Generalizing to 3-D is straightforward:
 1. Particle assignment: use NGP; or for PIC, particle is sphere.
 2. BCs: periodic, or use 3-D multipole expansion.
 3. Solve Poisson's equation in 3-D (see below).
 4. Interpolate \mathcal{F} in 3-D (easy).
- Poisson's equation in 3-D:

$$\frac{\partial^2 \Phi}{\partial x^2} + \frac{\partial^2 \Phi}{\partial y^2} + \frac{\partial^2 \Phi}{\partial z^2} = 4\pi G\rho.$$

- Discretize Φ in 3-D:

$$\Phi(x, y, z) \rightarrow \Phi_{i,j,k},$$

$$\rho(x, y, z) \rightarrow \rho_{i,j,k}.$$

- FDE becomes:

$$\frac{\Phi_{i-1,j,k} - 2\Phi_{i,j,k} + \Phi_{i+1,j,k}}{(\Delta x)^2} + \frac{\Phi_{i,j-1,k} - 2\Phi_{i,j,k} + \Phi_{i,j+1,k}}{(\Delta y)^2} + \frac{\Phi_{i,j,k-1} - 2\Phi_{i,j,k} + \Phi_{i,j,k+1}}{(\Delta z)^2} = 4\pi G\rho_{i,j,k}.$$

● Can be written in matrix form:

$$\begin{aligned} a_i \Phi_{i,j,k-1} &+ b_i \Phi_{i,j-1,k} + c_i \Phi_{i-1,j,k} + d_i \Phi_{i,j,k} + \\ &+ e_i \Phi_{i+1,j,k} + f_i \Phi_{i,j+1,k} + g_i \Phi_{i,j,k+1} = h_i, \end{aligned}$$

where $i = 1, \dots, N_x$, $j = 1, \dots, N_y$, $k = 1, \dots, N_z$ and

$$c_i = e_i = 1/(\Delta x)^2$$

$$d_i = -2 \left[(1/\Delta x)^2 + (1/\Delta y)^2 + (1/\Delta z)^2 \right]$$

$$b_i = f_i = 1/(\Delta y)^2$$

$$h_i = 4\pi G \rho_{i,j,k} \text{ (modulo BCs)}$$

$$a_i = g_i = 1/(\Delta z)^2$$

- Leads to very large sparse banded matrix:

$$\begin{bmatrix}
 d & e & & & f & & & g \\
 c & \cdot & \cdot & & & \cdot & & \cdot \\
 & \cdot & \cdot & \cdot & & \cdot & & g \\
 & & \cdot & \cdot & \cdot & & f & \\
 & & & \cdot & \cdot & \cdot & & \cdot \\
 b & & & \cdot & d & e & & \cdot \\
 & \cdot & & & c & d & \cdot & f \\
 & & \cdot & & & \cdot & \cdot & \cdot \\
 & & & b & & \cdot & \cdot & \cdot \\
 a & & & \cdot & & \cdot & \cdot & \cdot \\
 & \cdot & & & \cdot & & \cdot & \cdot & e \\
 & & a & & b & & c & d
 \end{bmatrix}$$

- Dimension is $(N_x N_y N_z) \times (N_x N_y N_z)!$

- \implies even very small problem (20^3) \rightarrow large matrix 8000×8000 .
- “Reasonable” sized problem (100^3) $\rightarrow 10^6 \times 10^6$ matrix!
- Clearly need efficient ways to solve matrix:
 1. Relaxation schemes — guess solution, then relax (Cf. *NRiC* §19.5–19.6).
 - E.g., “Successive Over-Relaxation” (SOR),
 - “Alternating-Direction Implicit” (ADI), multi-grid (use exact solution on coarse grid as initial guess for iterative solution on fine grid), etc.
 2. Sparse banded solvers, e.g., conjugate gradient method (*NRiC*, §2.7).
 3. Fourier methods — solution of FDE in Fourier space is very simple, then can inverse Fourier transform solution back to real space (*NRiC* §19.4).
 - Very powerful, but requires periodic BCs.

Summary: PM Method

- What is advantage of PM code?
 - Force solving scales as $\mathcal{O}(N_g)$, where N_g = number of mesh grid points.
 - Leapfrog scales as $\mathcal{O}(N_p)$, where N_p = number of particles.
 - Work associated with leapfrog \ll solving Poisson's equation.
∴ can afford very large N_p , e.g., N_p 10^{6-8} with $N_g \sim 10^{4-6}$.
 - Not good for correlated systems (in which 2-body encounters important) but great for uncorrelated systems (where it takes the place of softening).
